## Encryption Lab

Akarsh Shetty Umesh Mudelkadi  
317752264

```
[04/05/2019 19:15]Mudelkadi@VM1:~$ openssl aes-128-ecb -in pic_original.bmp -out ecb.bmp -K 00112233445566778889aabbccddeeff
```

```
[04/05/2019 19:17]Mudelkadi@VM1:~$ head -c 54 pic_original.bmp > header
[04/05/2019 19:19]Mudelkadi@VM1:~$ tail -c +55 ecb.bmp > body
[04/05/2019 19:19]Mudelkadi@VM1:~$ cat header body > new.bmp
[04/05/2019 19:19]Mudelkadi@VM1:~$ eog new.bmp
```

CBC

```
[04/05/2019 19:25]Mudelkadi@VM1:~$ openssl aes-128-cbc -in pic_original.bmp -out cbc.bmp -K 00112233445566778889aabbccddeeff -iv 0102030405060708
[04/05/2019 19:25]Mudelkadi@VM1:~$ head -c 54 pic_original.bmp > header
[04/05/2019 19:25]Mudelkadi@VM1:~$ tail -c +55 cbc.bmp > body
[04/05/2019 19:26]Mudelkadi@VM1:~$ cat header body > new.bmp
[04/05/2019 19:26]Mudelkadi@VM1:~$ eog new.bmp
```

From the above outputs of ECB and CBC we can infer that ECB doesn't encrypt properly and lets us know the actual message whereas CBC gives granular output thus not revealing the actual message. This is because in ECB all the similar plaintexts gives similar ciphertexts whereas the

inputs in CBC are XOR of previous ciphertext and current plaintext and this happens canonically.

4)

a)

```
[04/05/2019 20:38]Mudelkadi@VM1:~$ openssl aes-128-cbc -in f2.txt -out f2_cbc.txt -K 0011
2233445566778889aabbccddeeff -iv 0102030405060708
[04/05/2019 20:38]Mudelkadi@VM1:~$ openssl aes-128-cbc -in f3.txt -out f3_cbc.txt -K 0011
2233445566778889aabbccddeeff -iv 0102030405060708
[04/05/2019 20:38]Mudelkadi@VM1:~$ openssl aes-128-ecb -in f2.txt -out f2_ecb.txt -K 0011
2233445566778889aabbccddeeff
[04/05/2019 20:39]Mudelkadi@VM1:~$ openssl aes-128-ecb -in f3.txt -out f3_ecb.txt -K 0011
2233445566778889aabbccddeeff
[04/05/2019 20:39]Mudelkadi@VM1:~$ openssl aes-128-cfb -in f2.txt -out f2_cfb.txt -K 0011
2233445566778889aabbccddeeff
iv undefined
[04/05/2019 20:39]Mudelkadi@VM1:~$ openssl aes-128-cfb -in f2.txt -out f2_cfb.txt -K 0011
2233445566778889aabbccddeeff -iv 0102030405060708
[04/05/2019 20:39]Mudelkadi@VM1:~$ openssl aes-128-cfb -in f3.txt -out f3_cfb.txt -K 0011
2233445566778889aabbccddeeff -iv 0102030405060708
[04/05/2019 20:40]Mudelkadi@VM1:~$ openssl aes-128-ofb -in f2.txt -out f2_ofb.txt -K 0011
2233445566778889aabbccddeeff -iv 0102030405060708
[04/05/2019 20:40]Mudelkadi@VM1:~$ openssl aes-128-ofb -in f3.txt -out f3_ofb.txt -K 0011
2233445566778889aabbccddeeff -iv 0102030405060708
```

```
-rw-rw-r-- 1 seed seed 16 Apr 5 20:38 f2_cbc.txt
-rw-rw-r-- 1 seed seed 10 Apr 5 20:39 f2_cfb.txt
-rw-rw-r-- 1 seed seed 16 Apr 5 20:39 f2_ecb.txt
-rw-rw-r-- 1 seed seed 10 Apr 5 20:40 f2_ofb.txt
-rw-rw-r-- 1 seed seed 10 Apr 5 20:07 f2.txt
```

```
-rw-rw-r-- 1 seed seed 32 Apr 5 20:38 f3_cbc.txt
-rw-rw-r-- 1 seed seed 16 Apr 5 20:40 f3_cfb.txt
-rw-rw-r-- 1 seed seed 32 Apr 5 20:39 f3_ecb.txt
-rw-rw-r-- 1 seed seed 16 Apr 5 20:40 f3_ofb.txt
-rw-rw-r-- 1 seed seed 16 Apr 5 20:09 f3.txt
```

We can infer that padding doesn't happen with CFB and OFB, whereas padding happens for CBC and ECB until it reaches next multiple of 16 bytes.

b)

```
[04/05/2019 20:29]Mudelkadi@VM1:~$ cat f1.txt
anula[04/05/2019 20:29]Mudelkadi@VM1:~$ cat f2.txt
akarshetty[04/05/2019 20:29]Mudelkadi@VM1:~$ cat f3.txt
padminiumesharju[04/05/2019 20:29]M$ hexdump -C f1_aes_decrypt.txt
$: command not found
[04/05/2019 20:30]Mudelkadi@VM1:~$ hexdump -C f1_aes_decrypt.txt

00000060 6b 20 66 72 6f 6d 20 73 65 74 62 61 63 6b 73 20 | k from setbacks |
```

We can infer that after corrupting the 50<sup>th</sup> byte data, one block(3d ) gets corrupted while decrypting.

Therefore, there is 2 blocks changes in CBC and CFB while decrypting the corrupted 50<sup>th</sup> byte because it uses previous block for encryption but for OFB and ECB there is only 1 block change because it doesn't use previous block for encryption.

6.1)

```
[04/05/2019 22:30]Mudelkadi@VM1:~$ openssl aes-128-cbc -in pt1.txt -out ct1.txt -K 00112233445566778889aabbccddeeff -iv 0102030405060708

```

Pt1.txt is my plaintext. Ct1.txt and ct2.txt is ciphertext with same IV. Ct3.txt is ciphertext with different IV with just last 2 digits of IV interchanged. We can observe that ct1.txt and ct2.txt are same and it becomes easier for attacker to assume or crack the plaintext but when we use a different IV it gives totally a different ciphertext thus difficult to crack the plaintext.

ce356c3a478

Got XOR value for hexadecimal of plaintext 1 and ciphertext 1.

Thanks for using the calculator. [View help page.](#)

I. Input: hexadecimal (base 16) ▼

```
f001d8b622a8b99907b6353e2d2356c1d67e
2ce356c3a478
```

II. Input: hexadecimal (base 16) ▼

```
bf73bcd3509299d566c35b5d450337e1bb17
5f903fafc159
```

Calculate XOR

III. Output: hexadecimal (base 16) ▼

```
4f726465723a204c61756e63682061206d697
373696c6521
```

Got XOR value for previously calculated result and ciphertext 2.

**Enter the hexadecimal text to decode**

```
4f726465723a204c61756e63682061206d697373696c6521|
```

Convert

**The decoded string:**

```
Order: Launch a missile!
```

Got the plaintext 2 string value.

**Observation:** As the IV is same and the result is of XOR of plaintext and ciphertext of one string will be same for all the remaining strings. Thus, by getting the XOR value of plaintext and ciphertext of first string, the result got can be XORed with 2<sup>nd</sup> ciphertext to get the next plain text. The above pictures demonstrate how the result is obtained.

For CFB mode of encryption, the block encryption is XORed with the plaintext and sent as input to next string encryption and thus we need to know the next plaintext which will be XORed to get the ciphertext 2. Therefore we cannot obtain the plaintext in CFB mode.

6.3)

```
[04/08/2019 20:49]Mudelkadi@VM1:~$ hexdump -C samp_decry.txt
00000000  59 65 73 0d 0d 0d 0d 0d 0d 0d 0d 0d 0d 0d 0d  |Yes.....
....|
00000010
```

I. Input:

hexadecimal (base 16)

5965730d0d0d0d0d0d0d0d0d0d0d0d0d

II. Input:

```

**Answer:** First I got the decrypted value of “Yes” with padding as you can see in first picture. To find what is going inside the block for encryption, we can do this by XORing hex value of decrypted “Yes” with IV1 and IV2. The result is encrypted with IV2 for cancelling out IV2. Encrypting with the same key used and IV2 gives us the same ciphertext as used by original text. Thus using predictable IVs are not safe.

For info: I changed the same file samp.decry to last letter to c as we cannot just paste a string as we need hex value, therefore I used ghex command for changing.

7)

Code:

---

```

from Crypto.Cipher import *

plaintext = "This is a top secret."
plaintext+=chr(11) * 11 #should be padded to fit into whole block"
ciphertext="764aa26b55a4da654df6b19e4bce00f4ed05e09346fb0e762583cb7da2ac93a2"
IV="aabbccddeeff00998877665544332211"
decode_IV=IV.decode("hex")
f=open("words.txt","r")
l1=f.read().splitlines() #list of words in words.txt
for key in l1:
    word=key
    if len(word)>16: #as key doesn't exceed length 16
        continue
    if len(word)%16 !=0:
        length=len(word)
        while length%16!=0:
            word += "#" #add till the key becomes the size of
16                |length+=1
    new_ciphertext = AES.new(word,AES.MODE_CBC,decode_IV).encrypt(plaintext)
    nct_hex=str(new_ciphertext.encode("hex"))
    if (nct_hex==ciphertext):
        print('Key = '+key)

```

```

[04/08/2019 23:02]Mudelkadi@VM1:~$ sudo python progcrypto.py
Key = Syracuse
[04/08/2019 23:05]Mudelkadi@VM1:~$ █

```

Used words.txt for finding the actual key. Have converted values into HEX wherever needed. If the words length is greater than 16 they are not checked (as mentioned in the question that the key doesn't exceed length 16).
